

Chapter 9

Lie Groups as Spin Groups¹

9.1 Introduction

A Lie group, G , is a group that is also a differentiable manifold. So that if $g \in G$ and $x \in \mathfrak{R}^N$ then there is a differentiable mapping $\phi : \mathfrak{R}^N \rightarrow G$ so that for each $g \in G$ we can define a tangent space \mathcal{T}_g .

An example (the one we are most concerned with) of a Lie group is the group of $n \times n$ non-singular matrices. The coordinates of the manifold are simply the elements of the matrix so that the dimension of the group manifold is n^2 and the matrix is obviously a continuous differentiable function of its coordinates.

A Lie algebra is a vector space \mathfrak{g} with a binary operator $[\cdot, \cdot] : \mathfrak{g} \times \mathfrak{g} \rightarrow \mathfrak{g}$ called the *Lie bracket* which satisfies ($x, y, z \in \mathfrak{g}$ and $\alpha, \beta \in \mathfrak{R}$):

$$[ax + by, z] = a[x, z] + b[y, z], \quad (9.1)$$

$$[x, x] = 0, \quad (9.2)$$

$$[x, [y, z]] + [z, [x, y]] + [y, [z, x]] = 0. \quad (9.3)$$

Equations (9.1) and (9.2) imply $[x, y] = -[y, x]$, while eq (9.3) is the Jacobi identity.

The purpose of the following analysis is to show that the Lie algebra of the general linear group of dimension n over the real numbers (the group of $n \times n$ invertible matrices), $GL(n, \mathfrak{R})$, can

¹This chapter follows [5]

be represented by a rotation group in an appropriate vector space, \mathcal{M} (let m be the dimension of the new vector space). Furthermore, since the rotation group, $SO(m)$ can be represented by the spin group, $Spin(m)$, in the same vector space. Then by use of geometric algebra we can construct any rotor, $R \in Spin(m)$, as $R = e^{\frac{B}{2}}$ where B is a bi-vector in the geometric algebra of \mathcal{M} and the bi-vectors form a Lie algebra under the commutator product.

The main trick in doing this is to construct the appropriate vector space, \mathcal{M} , with subspaces isomorphic to \mathfrak{R}^n so that a rotation in \mathcal{M} is equivalent to a general linear transformation in a subspace of \mathcal{M} isomorphic to \mathfrak{R}^n . We might suspect that \mathcal{M} cannot be a Euclidean space since a general linear transformation can cause the input vector to grow as well as shrink.

9.2 Simple Examples

9.2.1 $SO(2)$ - Special Orthogonal Group of Order 2

The group is represented by all 2×2 real matrices² \underline{R} where³ $\underline{R}\underline{R}^T = \underline{I}$ and $\det(\underline{R}) = 1$. The group product is matrix multiplication and it is a group since if $\underline{R}_1\underline{R}_1^T = \underline{I}$ and $\underline{R}_2\underline{R}_2^T = \underline{I}$ then

$$(\underline{R}_1\underline{R}_2)(\underline{R}_1\underline{R}_2)^T = \underline{R}_1\underline{R}_2\underline{R}_2^T\underline{R}_1^T = \underline{R}_1\underline{I}\underline{R}_1^T = \underline{R}_1\underline{R}_1^T = \underline{I} \quad (9.4)$$

$$\det(\underline{R}_1\underline{R}_2) = \det(\underline{R}_1)\det(\underline{R}_2) = 1. \quad (9.5)$$

$SO(2)$ is also a Lie group since all $\underline{R} \in SO(2)$ can be represented as a continuous function of the coordinate θ :

$$\underline{R}(\theta) = \begin{bmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{bmatrix}. \quad (9.6)$$

In this case the spin representation of $SO(2)$ is trivial, namely⁴ $R(\theta) = e^{\frac{I}{2}\theta} = \cos\left(\frac{\theta}{2}\right) + I\sin\left(\frac{\theta}{2}\right)$, $R(\theta)^\dagger = e^{-\frac{I}{2}\theta} = \cos\left(\frac{\theta}{2}\right) - I\sin\left(\frac{\theta}{2}\right)$ where I is the pseudo-scalar for $\mathcal{G}(\mathfrak{R}^2)$. Then we have $\underline{R}(\theta)a = R(\theta)aR(\theta)^\dagger$.

²We denote linear transformations with an underbar.

³In this case \underline{I} is the identity matrix and not the pseudo scalar.

⁴For multivectors such as the rotor R there is no underbar. We have $\underline{R}(a) = \underline{R}a = RaR^\dagger$ where a is a vector.

9.2.2 $GL(2, \mathbb{R})$ - General Real Linear Group of Order 2

The group is represented by all 2×2 real matrices \underline{A} where $\det(\underline{A}) \neq 0$. Again the The group product is matrix multiplication and it is a group because if \underline{A} and \underline{B} are 2×2 real matrices then $\det(\underline{AB}) = \det(\underline{A}) \det(\underline{B})$ and if $\det(\underline{A}) \neq 0$ and $\det(\underline{B}) \neq 0$ then $\det(\underline{AB}) \neq 0$. Any member of the group is represented by the matrix $(a = (a^1, a^2, a^3, a^4) \in \mathbb{R}^4)$:

$$\underline{A}(a) = \begin{bmatrix} a^1 & a^2 \\ a^3 & a^4 \end{bmatrix}. \quad (9.7)$$

Thus any element $\underline{A} \in GL(2, \mathbb{R})$ is a continuous function of $a = (a^1, a^2, a^3, a^4)$. Thus $GL(2, \mathbb{R})$ is a four dimensional Lie group while $SO(2)$ is a one dimensional Lie group.

Another difference is that $SO(2)$ is compact while $GL(2, \mathbb{R})$ is not. $SO(2)$ is compact since for any convergent sequence (θ_i) ,

$$\lim_{i \rightarrow \infty} \underline{R}(\theta_i) \in SO(2).$$

$GL(2, \mathbb{R})$ is not compact since there is at least one convergent sequence (a_i) such that

$$\lim_{i \rightarrow \infty} \det(\underline{A}(a_i)) = 0.$$

After we develop the required theory we will calculate the spin representation of $GL(2, \mathbb{R})$.

9.3 The Grassmann Algebra

Let \mathcal{V}^n be an n -dimensional real vector space with basis $\{\mathbf{w}_i\} : 1 \leq i \leq n$ and \wedge is the outer (wedge) product for the geometric algebra define on \mathcal{V}^n . As before the geometric object

$$v_1 \wedge v_2 \wedge \dots \wedge v_k \quad (9.8)$$

is a k -blade in the Grassmann or the geometric algebra where the v_i 's are k independent vectors in \mathcal{V}_n and a linear combination of k -blades is called a k -vector. The space of all k -vectors is just all the k -grade multivectors in the geometric algebra $\mathcal{G}(\mathcal{V}_n)$. Denote the space of all k -vectors in \mathcal{V}^n by $\Lambda_n^k = \Lambda^k(\mathcal{V}^n)$ with

$$\dim(\Lambda_n^k) = \binom{n}{k} = \frac{n!}{k!(n-k)!}. \quad (9.9)$$

Letting $\Lambda_n^1 = \mathcal{V}^n$ and $\Lambda_n^0 = \Re$ the entire Grassmann algebra is a 2^n -dimensional space.⁵

$$\Lambda_n = \sum_{k=0}^n \Lambda_n^k. \quad (9.10)$$

The Grassmann algebra of a vector space \mathcal{V}^n is denoted by $\Lambda(\mathcal{V}^n)$.

9.4 The Dual Space to \mathcal{V}_n

The dual space \mathcal{V}^{n*} to \mathcal{V}^n is defined as follows. Let $\{\mathbf{w}_i\}$ be a basis for \mathcal{V}^n and define the basis, $\{\mathbf{w}_i^*\}$ for \mathcal{V}^{n*} by

$$\mathbf{w}_i^* \cdot \mathbf{w}_j = \frac{1}{2} \delta_{ij}. \quad (9.11)$$

Again the dual space \mathcal{V}^{n*} has its own Grassmann algebra $\Lambda^*(\mathcal{V}^n)$ given by

$$\Lambda^*(\mathcal{V}^n) = \Lambda_n^* = \sum_{k=0}^n \Lambda_n^{k*}. \quad (9.12)$$

$\Lambda^*(\mathcal{V}^n)$ can be represented as a geometric algebra by imposing the null metric condition $(\mathbf{w}_i^*)^2 = 0$ as in the case of $\Lambda(\mathcal{V}^n)$.

9.5 The Mother Algebra

From the base vector space and it's dual space one can construct a $2n$ dimensional vector space from the direct sum of the two vector spaces as defined in Appendix F

$$\Re^{n,n} \equiv \mathcal{V}^n \oplus \mathcal{V}^{n*} \quad (9.13)$$

⁵Consider the geometric algebra $\mathcal{G}(\mathcal{V}^n)$ of \mathcal{V}^n with a null basis $\{\mathbf{w}_i\} : \mathbf{w}_i^2 = 0, 1 \leq i \leq n$. Then

$$\begin{aligned} (\mathbf{w}_i + \mathbf{w}_j)^2 &= \mathbf{w}_i^2 + \mathbf{w}_i \mathbf{w}_j + \mathbf{w}_j \mathbf{w}_i + \mathbf{w}_j^2 \\ 0 &= \mathbf{w}_i \mathbf{w}_j + \mathbf{w}_j \mathbf{w}_i \\ \mathbf{w}_i \mathbf{w}_j &= -\mathbf{w}_j \mathbf{w}_i \\ 0 &= 2\mathbf{w}_i \cdot \mathbf{w}_j. \end{aligned}$$

If the basis set is null the metric tensor is null and $\mathbf{w}_i \mathbf{w}_j = \mathbf{w}_i \wedge \mathbf{w}_j$ even if $i = j$ and the geometric algebra is a Grassmann algebra.

with basis $\{\mathbf{w}_i, \mathbf{w}_i^*\}$. An orthogonal basis for $\mathfrak{R}^{n,n}$ can be constructed as follows (using equation 9.11):

$$\mathbf{e}_i = \mathbf{w}_i + \mathbf{w}_i^* \quad (9.14)$$

$$\bar{\mathbf{e}}_i = \mathbf{w}_i - \mathbf{w}_i^* \quad (9.15)$$

$$\begin{aligned} \mathbf{e}_i \cdot \mathbf{e}_j &= (\mathbf{w}_i + \mathbf{w}_i^*) \cdot (\mathbf{w}_j + \mathbf{w}_j^*) \\ &= \mathbf{w}_i \cdot \mathbf{w}_j + \mathbf{w}_i \cdot \mathbf{w}_j^* + \mathbf{w}_i^* \cdot \mathbf{w}_j + \mathbf{w}_i^* \cdot \mathbf{w}_j^* \\ &= \delta_{ij} \end{aligned} \quad (9.16)$$

$$\begin{aligned} \bar{\mathbf{e}}_i \cdot \bar{\mathbf{e}}_j &= (\mathbf{w}_i - \mathbf{w}_i^*) \cdot (\mathbf{w}_j - \mathbf{w}_j^*) \\ &= \mathbf{w}_i \cdot \mathbf{w}_j - \mathbf{w}_i \cdot \mathbf{w}_j^* - \mathbf{w}_i^* \cdot \mathbf{w}_j + \mathbf{w}_i^* \cdot \mathbf{w}_j^* \\ &= -\delta_{ij} \end{aligned} \quad (9.17)$$

$$\begin{aligned} \mathbf{e}_i \cdot \bar{\mathbf{e}}_j &= (\mathbf{w}_i + \mathbf{w}_i^*) \cdot (\mathbf{w}_j - \mathbf{w}_j^*) \\ &= \mathbf{w}_i \cdot \mathbf{w}_j - \mathbf{w}_i \cdot \mathbf{w}_j^* + \mathbf{w}_i^* \cdot \mathbf{w}_j - \mathbf{w}_i^* \cdot \mathbf{w}_j^* \\ &= 0. \end{aligned} \quad (9.18)$$

Thus $\mathfrak{R}^{n,n}$ can also be represented by the direct sum of an n -dimensional Euclidian vector space, E^n , and a n -dimensional anti-Euclidian vector space (square of all basis vectors is -1) \bar{E}^n

$$\mathfrak{R}^{n,n} = E^n \oplus \bar{E}^n. \quad (9.19)$$

In this case E^n and \bar{E}^n are orthogonal since $\mathbf{e}_i \cdot \bar{\mathbf{e}}_j = 0$. The geometric algebra of $\mathfrak{R}^{n,n}$ is defined and denoted by

$$\mathfrak{R}_{n,n} \equiv \mathcal{G}(\mathfrak{R}^{n,n}) \quad (9.20)$$

has dimension 2^{2n} with k -vector subspaces $\mathfrak{R}_{n,n}^k = \mathcal{G}^k(\mathfrak{R}^{n,n})$ and is called the *mother algebra*.

From the basis $\{\mathbf{e}_i, \bar{\mathbf{e}}_i\}$ we can construct $(p+q)$ -blades

$$E_{p,q} = E_p \wedge \bar{E}_q^\dagger = E_p \bar{E}_q^\dagger, \quad (9.21)$$

where⁶

$$E_p = \mathbf{e}_{i_1} \mathbf{e}_{i_2} \dots \mathbf{e}_{i_p} = E_{p,0} \quad 1 \leq i_1 < i_2 < \dots < i_p \leq n \quad (9.22)$$

$$\bar{E}_q = \bar{\mathbf{e}}_{j_1} \bar{\mathbf{e}}_{j_2} \dots \bar{\mathbf{e}}_{j_q} = \bar{E}_{0,q} \quad 1 \leq j_1 < j_2 < \dots < j_q \leq n. \quad (9.23)$$

⁶Since the $\{\mathbf{e}_i, \bar{\mathbf{e}}_i\}$ form an orthogonal set and specifying that no factors are repeated we can use the geometric product in equations 9.22 and 9.23 instead of the outer (wedge) product.

Each blade determines a projection of $\underline{E}_{p,q}$ of $\mathfrak{R}^{n,n}$ into a $(p+q)$ -dimensional subspace $\mathfrak{R}^{p,q}$ defined by (see section 5.1.2 and equation 1.42)⁷

$$\underline{E}_{p,q}a \equiv (a \cdot E_{p,q}) E_{p,q}^{-1} = \frac{1}{2} (a - (-1)^{p+q} E_{p,q}aE_{p,q}^{-1}). \quad (9.24)$$

A vector, a , is in $\mathfrak{R}^{p,q}$ if and only if

$$a \wedge E_{p,q} = 0 = aE_{p,q} + (-1)^{p+q} E_{p,q}a. \quad (9.25)$$

For $p+q=n$, the blade $E_{p,q}$ determines a split of $\mathfrak{R}^{n,n}$ into orthogonal subspaces with *complementary signature*⁸, as expressed by

$$\mathfrak{R}^{n,n} = \mathfrak{R}^{p,q} \oplus \bar{\mathfrak{R}}^{p,q}. \quad (9.26)$$

For the case of $q=0$ equation 9.24 can be written as

$$\underline{E}_na = \frac{1}{2} (a + a^*), \quad (9.27)$$

where a^* is defined by

$$a^* \equiv (-1)^{n+1} E_naE_n^{-1}. \quad (9.28)$$

It follows immediately that $\mathbf{e}_i^* = \mathbf{e}_i$ and $(\bar{\mathbf{e}}_i)^* = -\bar{\mathbf{e}}_i$.⁹ The split of $\mathfrak{R}^{n,n}$ given by equation 9.13 cannot be constructed as the split in equation 9.19 since the vectors expanded in the $\{\mathbf{w}_i, \mathbf{w}_j^*\}$ basis cannot be normalized since they are null vectors. Instead consider a bivector, K in $\mathfrak{R}^{n,n}$

$$K = \sum_{i=0}^n K_i, \quad (9.29)$$

where the K_i are distinct commuting blades, $K_i \times K_j = 0$ (commutator product), normalized to $K_i^2 = 1$. The bivector K defines the automorphism $\underline{K} : \mathfrak{R}^{n,n} \rightarrow \mathfrak{R}^{n,n}$

$$\bar{a} = \underline{K}a \equiv a \times K = a \cdot K. \quad (9.30)$$

⁷The underbar notation as in $\underline{E}_{p,q}(a)$ allows one to distinguish linear operators from elements in the algebra such as $E_{p,q}$.

⁸The signature of $\mathfrak{R}^{p,q}$ is (p, q) as opposed to $\bar{\mathfrak{R}}^{p,q}$ with signature (q, p) .

⁹This is obvious by

$$\begin{aligned} \mathbf{e}_i^* &= (-1)^{n+1} E_n \mathbf{e}_i E_n^{-1} = (-1)^{n+1} (-1)^{n-1} \mathbf{e}_i E_n E_n^{-1} = (-1)^{2n} \mathbf{e}_i = \mathbf{e}_i, \\ (\bar{\mathbf{e}}_i)^* &= (-1)^{n+1} E_n (\bar{\mathbf{e}}_i) E_n^{-1} = (-1)^{n+1} (-1)^n (\bar{\mathbf{e}}_i) E_n E_n^{-1} = (-1)^{2n+1} (\bar{\mathbf{e}}_i) = -(\bar{\mathbf{e}}_i). \end{aligned}$$

This maps every vector a into the vector \bar{a} which is called the *complement* of a with respect to K .

Each K_i is a bivector blade that defines a two dimensional Minkowski (since $K_i^2 = 1$) subspace of $\Re^{n,n}$. Since the blades commute, $K_i \times K_j = 0$, they define disjoint subspaces of $\Re^{n,n}$ and since there are n of them they span $\Re^{n,n}$. Since $K_i^2 = 1$ there exists an orthonormal Minkowski basis e_i and \bar{e}_i such that

$$e_i \cdot \bar{e}_j = 0, \quad i \neq j, \quad (9.31)$$

$$e_i \cdot e_i = -\bar{e}_i \cdot \bar{e}_i = 1. \quad (9.32)$$

Then if $a \in \Re^{n,n}$ and using equations 9.31, 9.32, and from appendix B equations B.2 and B.5 we have

$$a \cdot K_i = a \cdot (e_i \bar{e}_i) = -(a \cdot \bar{e}_i) e_i + (a \cdot e_i) \bar{e}_i, \quad (9.33)$$

$$\begin{aligned} (a \cdot K_i) \cdot K_i &= (a \cdot (e_i \bar{e}_i)) \cdot (e_i \bar{e}_i) \\ &= (a \cdot e_i) e_i - (a \cdot \bar{e}_i) \bar{e}_i \\ &= (a \cdot e_i) e_i + (a \cdot \bar{e}_i) \bar{e}_i = a, \end{aligned} \quad (9.34)$$

$$\begin{aligned} (a \cdot K_i) \cdot K_j &= ((a \cdot \bar{e}_i) (e_i \cdot \bar{e}_j) - (a \cdot e_i) (\bar{e}_i \cdot \bar{e}_j)) e_j \\ &\quad + ((a \cdot e_i) (\bar{e}_i \cdot e_j) - (a \cdot \bar{e}_i) (e_i \cdot e_j)) \bar{e}_j = 0, \quad \forall i \neq j \end{aligned} \quad (9.35)$$

Then

$$\underline{K}a = \sum_{i=1}^n a \cdot K_i = \sum_{i=1}^n ((a \cdot e_i) \bar{e}_i - (a \cdot \bar{e}_i) e_i) \quad (9.36)$$

and¹⁰

$$\begin{aligned}
\underline{K}^2 a &= \sum_{j=1}^n \left(\sum_{i=1}^n a \cdot K_i \right) \cdot K_j \\
&= \sum_{j=1}^n \sum_{i=1}^n (a \cdot K_i) \cdot K_j \\
&= \sum_{i=1}^n (a \cdot K_i) \cdot K_i \\
&= \sum_{i=1}^n ((a \cdot \mathbf{e}_i) \mathbf{e}_i - (a \cdot \bar{\mathbf{e}}_i) \bar{\mathbf{e}}_i) \\
&= \sum_{i=1}^n ((a \cdot \mathbf{e}^i) \mathbf{e}_i + (a \cdot \bar{\mathbf{e}}^i) \bar{\mathbf{e}}_i) \\
&= a.
\end{aligned} \tag{9.37}$$

Also

$$\begin{aligned}
a \cdot \bar{a} &= \sum_{i=1}^n a \cdot (a \cdot K_i) \\
&= \sum_{i=1}^n a \cdot ((a \cdot \mathbf{e}_i) \bar{\mathbf{e}}_i - (a \cdot \bar{\mathbf{e}}_i) \mathbf{e}_i) \\
&= \sum_{i=1}^n ((a \cdot \mathbf{e}_i) (a \cdot \bar{\mathbf{e}}_i) - (a \cdot \bar{\mathbf{e}}_i) (a \cdot \mathbf{e}_i)) \\
&= 0,
\end{aligned} \tag{9.38}$$

$$a^2 = \sum_{i=1}^n ((a \cdot \mathbf{e}_i)^2 - (a \cdot \bar{\mathbf{e}}_i)^2), \tag{9.39}$$

$$\bar{a}^2 = \sum_{i=1}^n ((a \cdot \bar{\mathbf{e}}_i)^2 - (a \cdot \mathbf{e}_i)^2), \tag{9.40}$$

$$a^2 + \bar{a}^2 = 0. \tag{9.41}$$

Thus defining

$$a_{\pm} \equiv a \pm \bar{a} = a \pm \underline{K}a = a \pm a \cdot K, \tag{9.42}$$

¹⁰Remember that since K_i defines a Minkowski subspace we have for the reciprocal basis $\mathbf{e}^i = \mathbf{e}_i$ and $\bar{\mathbf{e}}^i = -\bar{\mathbf{e}}_i$.

we have

$$(a_{\pm})^2 = 0, \quad (9.43)$$

$$a_+ \cdot a_- = a^2 - \bar{a}^2 = 2 \sum_{i=1}^n (a \cdot e_i)^2. \quad (9.44)$$

Thus the sets $\{a_+\}$ and $\{a_-\}$ of all such vectors are dual n -dimensional vector spaces, so K determines the desired null space decomposition of the form in equation 9.13 without referring to a vector basis.¹¹

The K for a given $\mathfrak{R}^{n,n}$ is constructed from the basis given in equations 9.14 and 9.15. Then we have from equation 9.36

$$\underline{K}e_i = \bar{e}_i, \quad (9.45)$$

$$\underline{K}\bar{e}_i = e_i. \quad (9.46)$$

Also from equation 9.36

$$\begin{aligned} \underline{K}w_i &= (w_i \cdot e_i) \bar{e}_i - (w_i \cdot \bar{e}_i) e_i, \\ &= \frac{1}{2} (((e_i + \bar{e}_i) \cdot e_i) \bar{e}_i - ((e_i + \bar{e}_i) \cdot \bar{e}_i) e_i), \\ &= \frac{1}{2} (\bar{e}_i + e_i), \\ &= w_i, \end{aligned} \quad (9.47)$$

$$\begin{aligned} \underline{K}w_i^* &= (w_i^* \cdot e_i) \bar{e}_i - (w_i^* \cdot \bar{e}_i) e_i, \\ &= \frac{1}{2} (((e_i - \bar{e}_i) \cdot e_i) \bar{e}_i - ((e_i - \bar{e}_i) \cdot \bar{e}_i) e_i), \\ &= -\frac{1}{2} (e_i - \bar{e}_i), \\ &= -w_i^*. \end{aligned} \quad (9.48)$$

The basis $\{w_i, w_i^*\}$ is called a *Witt basis* in the theory of quadratic forms.

¹¹The properties $K_i \times K_j = 0$ and $K_i^2 = 1$ allows us to construct K from the basis $\{e_i, \bar{e}_i\}$, but do not specify any particular basis.

9.6 The General Linear Group as a Spin Group

We will now use the results in section 1.15 and the extension of a linear vector function to blades (equation 1.77)¹² and the geometric algebra definition of the determinant of a linear transformation (equation 1.79)¹³.

We are concerned here with linear transformations on $\mathfrak{R}^{n,n}$ and its subspaces, especially orthogonal transformations. An orthogonal transformation \underline{R} is defined by the property

$$(\underline{R}a) \cdot (\underline{R}b) = a \cdot b \quad (9.49)$$

\underline{R} is called a rotation if $\det(\underline{R}) = 1$, that is, if

$$\underline{R}E_{n,n} = E_{n,n}, \quad (9.50)$$

where $E_{n,n} = E_n \bar{E}_n^\dagger$ is the pseudoscalar for $\mathfrak{R}_{n,n}$ (equation 9.21). These rotations form a group called the *special orthogonal group* $\text{SO}(n)$.

From section 1.10 we know that every rotation can be expressed by the canonical form

$$\underline{R}a = RaR^\dagger, \quad (9.51)$$

where R is an even multivector (*rotor*) satisfying

$$RR^\dagger = 1. \quad (9.52)$$

The rotors form a multiplicative group called the *spin group* or *spin representation* of $\text{SO}(n)$, and it is denoted by $\text{Spin}(n)$. $\text{Spin}(n)$ is said to be a double covering of $\text{SO}(n)$, since equation 9.51 shows that both $\pm R$ correspond to the same \underline{R} .

From equation 9.52 it follows that $R^{-1} = R^\dagger$ and that the inverse of the rotation is

$$\underline{R}^\dagger a = R^\dagger a R. \quad (9.53)$$

This implies that from the definition of the adjoint (using **RR5** in appendix C)

$$a \cdot (\underline{R}b) = \langle a R b R^\dagger \rangle = \langle b R^\dagger a R \rangle = b \cdot (\underline{R}^\dagger a). \quad (9.54)$$

The adjoint of a rotation is equal to its inverse.

¹² $\underline{f}(a \wedge b \wedge \dots) = \underline{f}(a) \wedge \underline{f}(b) \wedge \dots$

¹³ $\underline{f}(I) = \det(\underline{f}) I$ where I is the pseudoscalar.

“It can be shown that every rotor can be expressed in exponential form

$$R = \pm e^{\frac{1}{2}B}, \text{ with } R^\dagger = \pm e^{-\frac{1}{2}B}, \quad (9.55)$$

where B is a bivector (section 1.10.2) called the generator of R or \underline{R} , and the minus sign can usually be eliminated by a change in the definition of B . Thus every bivector determines a unique rotation. The bivector generators of a spin or rotation group form a Lie algebra under the commutator product. **This reduces the description of Lie groups to Lie algebras.** The Lie algebra of $\text{SO}(n)$ and $\text{Spin}(n)$ is designated by $\mathfrak{so}(n)$. It consists of the entire bivector space $\mathfrak{R}_{n,n}^2$. Our task will be to prove that and develop a systematic way to find them.

Lie groups are classified according to their invariants. For the *classical groups* the invariants are nondegenerate bilinear (quadratic) forms. Geometric algebra supplies us with a simpler alternative of invariants, namely, the multivectors which determine the bilinear forms. As emphasized in reference [4], every bilinear form can be written as $a \cdot (\underline{Q}(b))$ where \underline{Q} is a linear operator, and the form is nondegenerate if \underline{Q} is nonsingular (i.e., $\det(\underline{Q}) \neq 0$).¹⁴

Q is invariant under a rotation \underline{R} if

$$(\underline{R}a) \cdot (\underline{Q}\underline{R}b) = a \cdot (\underline{Q}b). \quad (9.56)$$

Using equation 9.54 transforms equation 9.56 to

$$\begin{aligned} (\underline{R}a) \cdot (\underline{Q}\underline{R}b) &= a \cdot (\underline{Q}b), \\ (\underline{Q}\underline{R}b) \cdot (\underline{R}a) &= a \cdot (\underline{Q}b), \\ a \cdot (\underline{R}^\dagger (\underline{Q}\underline{R}b)) &= a \cdot (\underline{Q}b), \\ a \cdot (\underline{R}^\dagger \underline{Q} \underline{R}b) &= a \cdot (\underline{Q}b), \end{aligned} \quad (9.57)$$

or since the a and b in equation 9.57 are arbitrary

$$\underline{R}^\dagger \underline{Q} \underline{R} = \underline{Q} = \underline{R} \underline{Q} \underline{R}^\dagger, \quad (9.58)$$

$$\underline{R} \underline{R}^\dagger \underline{Q} \underline{R} = \underline{R} \underline{Q}, \quad (9.59)$$

$$\underline{Q} \underline{R} = \underline{R} \underline{Q}. \quad (9.60)$$

Thus the invariance group of consists of those rotations which commute with Q .

¹⁴From reference [5].

This is obviously a group since if

$$\underline{R_1} \underline{Q} = \underline{Q} \underline{R_1}, \quad (9.61)$$

$$\underline{R_2} \underline{Q} = \underline{Q} \underline{R_2}, \quad (9.62)$$

then

$$\underline{R_1 R_2} \underline{Q} = \underline{R_1} \underline{Q} \underline{R_2}, \quad (9.63)$$

$$\underline{R_1 R_2} \underline{Q} = \underline{Q} \underline{R_1 R_2}. \quad (9.64)$$

As a specific case consider the quadratic form where $\underline{Q}b = b^*$. Then

$$\underline{Q}b = (-1)^{n+1} E_n b E_n^{-1}, \quad (9.65)$$

$$\underline{Q} \underline{R} b = (-1)^{n+1} E_n R b R^\dagger E_n^{-1},$$

$$\underline{R} \underline{Q} b = (-1)^{n+1} R E_n b E_n^{-1} R^\dagger,$$

$$E_n R b R^\dagger E_n^{-1} = R E_n b E_n^{-1} R^\dagger,$$

$$E_n R = R E_n,$$

$$E_n = R E_n R^\dagger. \quad (9.66)$$

Thus, the invariance of the bilinear form $a \cdot b^*$ is equivalent to the invariance of the n -blade E_n .

We can determine a representation for R by noting the generators of any rotation in $\mathfrak{R}^{n,n}$ can be written in the form

$$\begin{aligned} R &= e^{\frac{\theta}{2} \mathbf{uv}}, \\ &= \left\{ \begin{array}{c} \cos(\theta/2) \\ \cosh(\theta/2) \end{array} \right\} + \left\{ \begin{array}{c} \sin(\theta/2) \\ \sinh(\theta/2) \end{array} \right\} \mathbf{uv}, \\ &= \left\{ \begin{array}{c} \cos(\theta/2) \\ \cosh(\theta/2) \end{array} \right\} + \left\{ \begin{array}{c} \sin(\theta/2) \\ \sinh(\theta/2) \end{array} \right\} \sum_{i < j} (u^i \mathbf{e}_i + \bar{u}^i \bar{\mathbf{e}}_i) (v^j \mathbf{e}_j + \bar{v}^j \bar{\mathbf{e}}_j), \end{aligned} \quad (9.67)$$

where $\mathbf{u} \cdot \mathbf{v} = 0$ and $|(\mathbf{uv})^2| = 1$. Equation (9.67) is what makes corresponding the Lie algebras with the bivector commutator algebra possible and also allows one to calculate the generators of the corresponding Lie group. The generators of the most general rotation in $\mathfrak{R}^{n,n}$ are $\mathbf{e}_i \mathbf{e}_j$, $\bar{\mathbf{e}}_i \mathbf{e}_j$, and $\bar{\mathbf{e}}_i \bar{\mathbf{e}}_j$. The question is which of these generators commute with E_n . The answer is

$$\mathbf{e}_i \mathbf{e}_j E_n = E_n \mathbf{e}_i \mathbf{e}_j \quad (9.68)$$

$$\mathbf{e}_i \bar{\mathbf{e}}_j E_n = -E_n \mathbf{e}_i \bar{\mathbf{e}}_j \quad (9.69)$$

$$\bar{\mathbf{e}}_i \bar{\mathbf{e}}_j E_n = E_n \bar{\mathbf{e}}_i \bar{\mathbf{e}}_j. \quad (9.70)$$

Equation 9.70 is obvious since \bar{e}_i and \bar{e}_j give the same number of sign flips, n , in passing through E_n totalling $2n$ an even number. Likewise, in equation 9.68 as e_i and e_j give the same number of sign flips, $n - 1$, in passing through E_n totalling $2(n - 1)$ an even number. In equation 9.69 e_i produces $n - 1$ sign flips in traversing E_n and \bar{e}_j produces n sign flips for the same traverse so that the total number of sign flips is $2n - 1$ and odd number.

Thus the required rotation generators for R are

$$e_{ij} = e_i e_j, \text{ for } i < j = 1, \dots, n, \quad (9.71)$$

$$\bar{e}_{ij} = \bar{e}_i \bar{e}_j, \text{ for } i < j = 1, \dots, n. \quad (9.72)$$

Also note that since $e_{ij} \times \bar{e}_{kl} = 0$, the barred and unbarred generators commute. Any generator in the algebra can be written in the form

$$B = \alpha : e + \beta : \bar{e}, \quad (9.73)$$

where

$$\alpha : e \equiv \sum_{i < j} \alpha^{ij} e_{ij}, \quad (9.74)$$

and the α^{ij} are scalar coefficients. So that $\alpha : e$ is the generator for any rotation in \mathfrak{R}^n and $\beta : \bar{e}$ is the generator for any rotation in $\bar{\mathfrak{R}}^n$. The corresponding group rotor is (we can factor the exponent since e and \bar{e} generators commute)

$$R = e^{\frac{1}{2}(\alpha:e+\beta:\bar{e})} = e^{\frac{1}{2}\alpha:e} e^{\frac{1}{2}\beta:\bar{e}}. \quad (9.75)$$

This is the spin representation of the product group $SO(n) \otimes SO(n)$.

In most cases the generators of the invariance group are not as obvious and in the case of the $a \cdot b^*$ form. Thus we need some general methods for such determinations. Consider a skew-symmetric bilinear form \underline{Q} ¹⁵

$$a \cdot (\underline{Q}b) = -b \cdot (\underline{Q}a). \quad (9.76)$$

The form \underline{Q} can be written

$$a \cdot (\underline{Q}b) = a \cdot (b \cdot Q) = (a \wedge b) \cdot Q, \quad (9.77)$$

¹⁵This selection is done with malice aforethought. To generate the members of $GL(n, \mathfrak{R})$ we do not need the most general linear transformation on $\mathfrak{R}^{n,n}$ since the dimension of that group is $4n^2$ and not the n^2 of $GL(n, \mathfrak{R})$.

where Q is a bivector.¹⁶ We say that the bivector Q is *involutory* if \underline{Q} is nonsingular and

$$\underline{Q}^2 = \pm \underline{1}. \quad (9.78)$$

Note that the operator equation 9.78 only applies to vectors.

Note that

$$\begin{aligned} (\underline{R}a \wedge \underline{R}b) \cdot Q &= \underline{R}(a \wedge b) \cdot Q \\ &= (R(a \wedge b) R^\dagger) \cdot Q \\ &= \langle R(a \wedge b) R^\dagger Q \rangle \\ &= \langle (a \wedge b) R^\dagger Q R \rangle \\ &= (a \wedge b) \cdot (\underline{R}^\dagger Q). \end{aligned} \quad (9.79)$$

Then equation 9.77 gives for a stability condition

$$\begin{aligned} (\underline{R}a) \cdot (\underline{Q}Rb) &= a \cdot (\underline{Q}b), \\ ((\underline{R}a) \cdot (\underline{R}b)) \cdot Q &= (a \wedge b) \cdot Q, \\ ((\underline{R}a) \wedge (\underline{R}b)) \cdot Q &= \\ \underline{R}(a \wedge b) \cdot Q &= \\ \langle R(a \wedge b) R^\dagger Q \rangle &= \\ \langle (a \wedge b) R^\dagger Q R \rangle &= \\ (a \wedge b) \cdot (\underline{R}^\dagger Q R) &= (a \wedge b) \cdot Q, \\ R^\dagger Q R &= Q. \\ QR &= RQ \end{aligned} \quad (9.80)$$

From equation 9.80 we have that generators of the stability group $G(Q)$ for Q must commute with Q . To learn more about this requirement, we study the commutator of Q with an arbitrary

¹⁶This is obvious from the properties of the bilinear form that if $a \cdot (\underline{Q}b) = (a \wedge b) \cdot Q$ then $a \cdot (\underline{Q}b)$ is linear in a and b and is skew-symmetric

$$\begin{aligned} b \cdot (\underline{Q}a) &= (b \wedge a) \cdot Q \\ &= -(a \wedge b) \cdot Q \\ &= -a \cdot (\underline{Q}b) \end{aligned}$$

Finally the maximum number of free parameters (coefficients) for the bivector, Q , in an n -dimensional space is $\binom{n}{2} = \frac{n(n-1)}{2}$. This is also the number of independent coefficients in the $n \times n$ antisymmetric matrix that represents the skew-symmetric bilinear form.

bivector blade $a \wedge b$. Since $a \wedge b = a \times b$ and $a \times Q = a \cdot Q$ the Jacobi identity gives

$$\begin{aligned}
 (a \wedge b) \times Q &= (a \times b) \times Q, \\
 &= (a \times Q) \times b + a \times (b \times Q), \\
 &= (a \times Q) \wedge b + a \wedge (b \times Q), \\
 &= (a \cdot Q) \wedge b + a \wedge (b \cdot Q), \\
 &= (\underline{Q}a) \wedge b + a \wedge (\underline{Q}b),
 \end{aligned} \tag{9.81}$$

and then

$$((a \wedge b) \times Q) \times Q = ((\underline{Q}a) \wedge b + a \wedge (\underline{Q}b)) \times Q. \tag{9.82}$$

Now using the Jacobi identity and the extension of linear functions to blades we have

$$\begin{aligned}
 ((\underline{Q}a) \wedge b) \times Q &= ((\underline{Q}a) \times b) \times Q, \\
 &= (\underline{Q}a) \times (b \times Q) - b \times ((\underline{Q}a) \times Q), \\
 &= (\underline{Q}a) \wedge (b \cdot Q) - b \wedge ((\underline{Q}a) \cdot Q), \\
 &= (\underline{Q}a) \wedge (\underline{Q}b) - b \wedge (\underline{Q}^2 a), \\
 &= (\underline{Q}^2 a) \wedge b + \underline{Q}(a \wedge b).
 \end{aligned} \tag{9.83}$$

Similarly

$$(a \wedge (\underline{Q}b)) \times Q = \underline{Q}(a \wedge b) + a \wedge (\underline{Q}^2 b), \tag{9.84}$$

so that, since Q is involutory ($\underline{Q}^2 = \pm 1$)

$$\begin{aligned}
 ((a \wedge b) \times Q) \times Q &= (\underline{Q}^2 a) \wedge b + 2\underline{Q}(a \wedge b) + a \wedge (\underline{Q}^2 b), \\
 &= 2(\underline{Q}(a \wedge b) \pm a \wedge b).
 \end{aligned} \tag{9.85}$$

By linearity and superposition since equation 9.85 holds for any blade $a \wedge b$ it also holds for any bivector (superposition of 2-blades) B so that

$$(B \times Q) \times Q = 2(\underline{Q}B \pm B). \tag{9.86}$$

If B commutes with Q then $B \times Q = 0$ and

$$\underline{Q}B \pm B = 0, \tag{9.87}$$

$$\underline{Q}B = \mp B. \tag{9.88}$$

Thus the generators of $G(Q)$ are the eigenbivectors of \underline{Q} with eigenvalues ∓ 1 .

Now define the bivectors $E^\pm(a, b)$ and $F(a, b)$ by

$$E^\pm(a, b) \equiv a \wedge b \pm (\underline{Q}a) (\underline{Q}b), \quad (9.89)$$

$$F(a, b) \equiv (\underline{Q}a) \wedge b - a \wedge (\underline{Q}b). \quad (9.90)$$

Then using equation 9.81 we get

$$\begin{aligned} E^\pm(a, b) \times Q &= (\underline{Q}a) \wedge b + a \wedge (\underline{Q}b) \mp (\underline{Q}^2a) \wedge (\underline{Q}b) \mp (\underline{Q}a) \wedge (\underline{Q}^2b), \\ &= (\underline{Q}a) \wedge b + a \wedge (\underline{Q}b) - a \wedge (\underline{Q}b) - (\underline{Q}a) \wedge b, \\ &= 0, \end{aligned} \quad (9.91)$$

$$\begin{aligned} F(a, b) \times Q &= (\underline{Q}a) \wedge (\underline{Q}b) + a \wedge (\underline{Q}^2b) - (\underline{Q}^2a) \wedge b - (\underline{Q}a) \wedge (\underline{Q}b), \\ &= \pm a \wedge b \mp a \wedge b, \\ &= 0. \end{aligned} \quad (9.92)$$

Thus $E^\pm(a, b)$ and $F(a, b)$ are the generators of the stability group for Q . A basis for the Lie algebra is obtained by inserting basis vectors for a and b . The commutation relations for the generators $E^\pm(a, b)$ and $F(a, b)$ can be found from equations 9.89, 9.90, and B.13. Evaluation of the commutation relations is simplified by using the eigenvectors of \underline{Q} for a basis, so it is best to defer the task until \underline{Q} is completely specified.

As a concrete example let $Q = K$ where K is from equation 9.29 and use equations 9.45 and 9.46 to get¹⁷

$$\begin{aligned} E_{ij} &= E^+(e_i, e_j) = e_i \wedge e_j - (\underline{K}e_i) \wedge (\underline{K}e_j), \\ &= e_i e_j - \bar{e}_i \bar{e}_j \quad (i < j), \end{aligned} \quad (9.93)$$

$$\begin{aligned} F_{ij} &= F(e_i, e_j) = e_i \wedge (\underline{K}e_j) - (\underline{K}e_i) \wedge e_j, \\ &= e_i \bar{e}_j - \bar{e}_i e_j \quad (i < j), \end{aligned} \quad (9.94)$$

$$K_i = \frac{1}{2} F_{ii} = e_i \bar{e}_i. \quad (9.95)$$

The stability group of K can be identified with the *general linear group* $GL(n, \Re)$. First we must show that \underline{K} does not mix the subspaces \mathcal{V}^n and \mathcal{V}^{n*} of $\Re^{n,n}$. Using equations 9.47 and 9.48 we have (where W_n and W_n^* are the pseudoscalars for \mathcal{V}^n and \mathcal{V}^{n*}).

$$W_n = w_1 \dots w_n, \quad (9.96)$$

$$W_n^* = w_1^* \dots w_n^* \quad (9.97)$$

$$\underline{K}(W_n) = W_n, \quad (9.98)$$

$$\underline{K}(W_n^*) = (-1)^n W_n^*. \quad (9.99)$$

¹⁷Since $\underline{K}^2 = 1$ we only need consider $E^+(e_i, e_j)$.

Thus when restricted to \mathcal{V}^n or \mathcal{V}^{n*} , \underline{K} is non-singular since the $\det(\underline{K}) \neq 0$.
